Problem Statement

- Detect cracks in concrete structures
- Applications: bridges, tunnels, buildings
- Challenges:
  - Very thin structures
  - Noise and low contrast
  - Class imbalance

Figure: cracks in concrete structures

Image Segmentation

- Pixel-wise classification
- Input: image
- Output: binary mask (binary segmentation)
- Each pixel labeled as crack / no crack

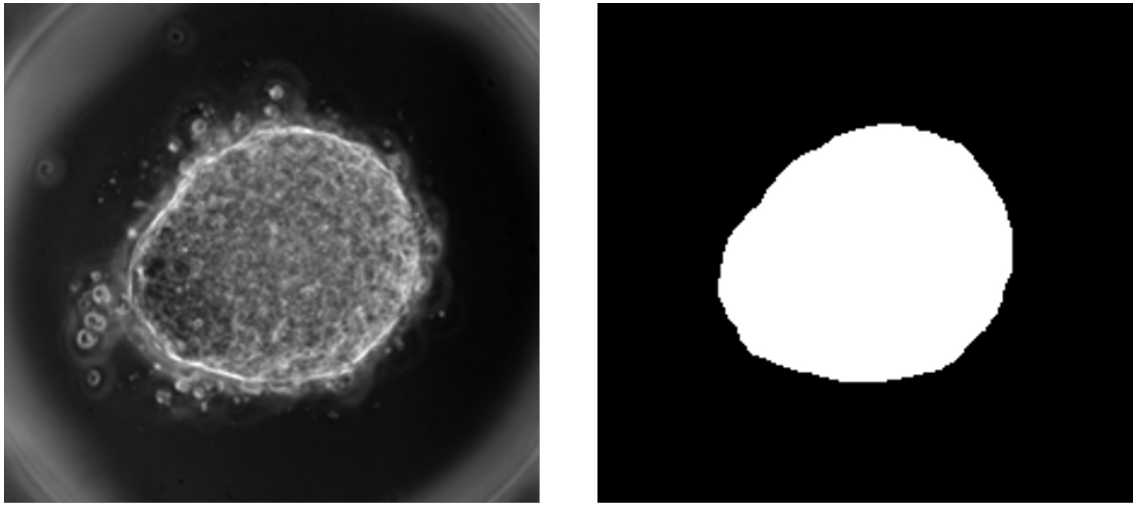

Figure: Example of image and corresponding segmentation mask

U-Net

- CNN architecture for segmentation
- Encoder: extracts features
- Bottleneck: middleware
- Decoder: reconstructs segmentation
- Skip connections preserve spatial details

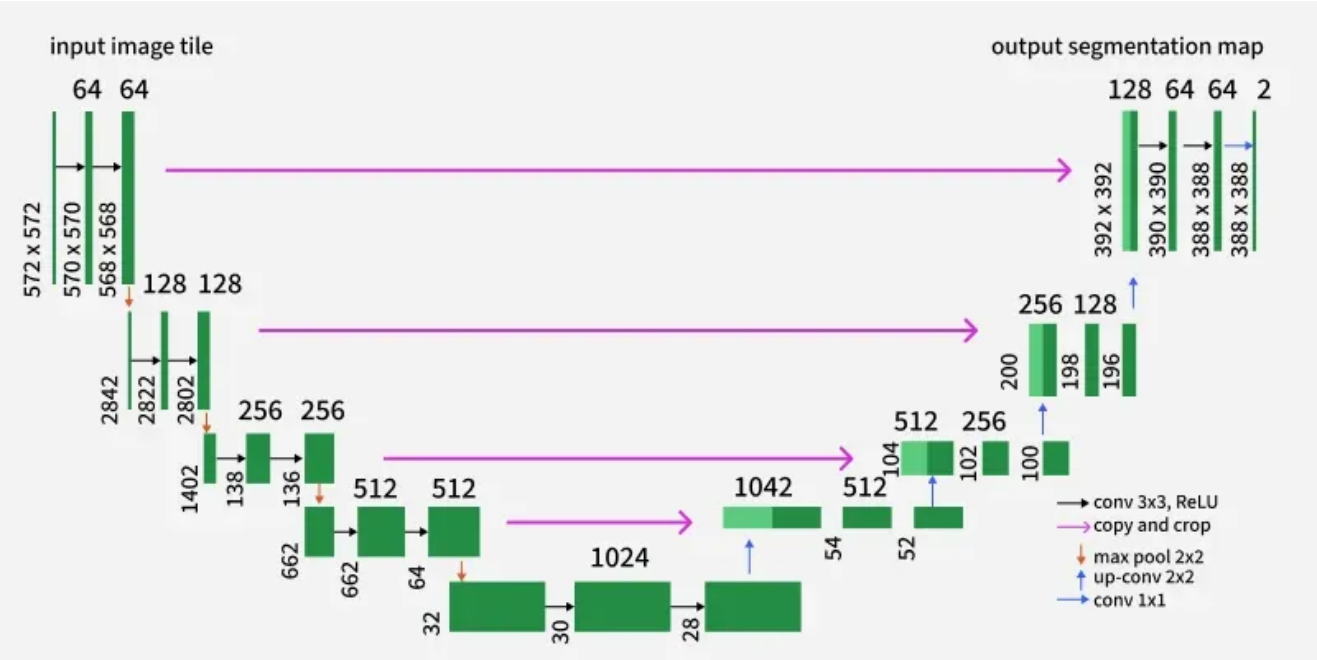

Figure: U-Net architecture

U-Net++

- Improved version of U-Net : Nested skip connections
- Better feature fusion
- Higher accuracy but more complexity

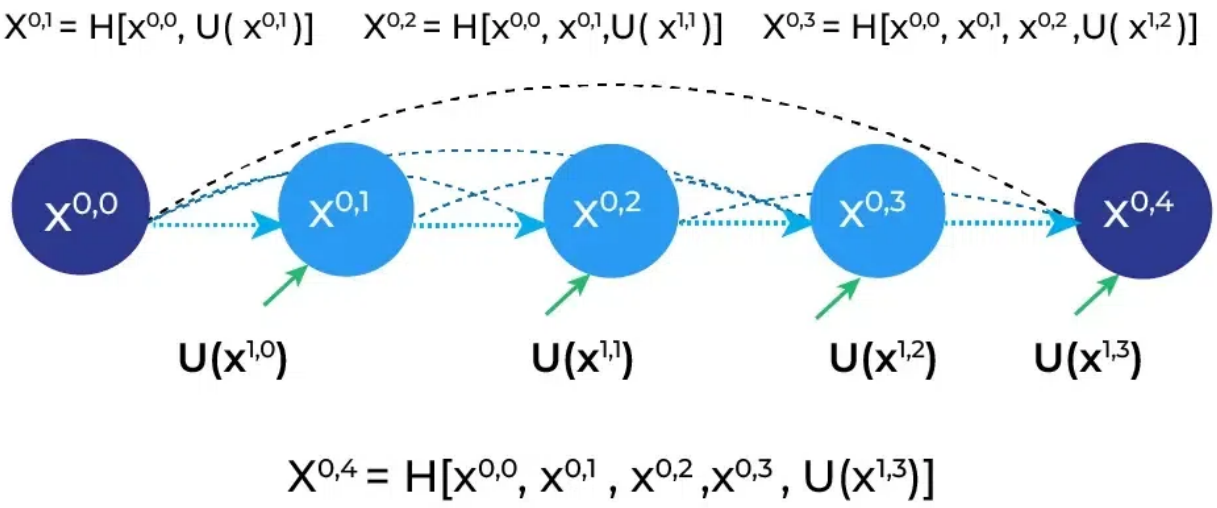

Figure: U-Net++ dense skip pathways

Teacher vs Student

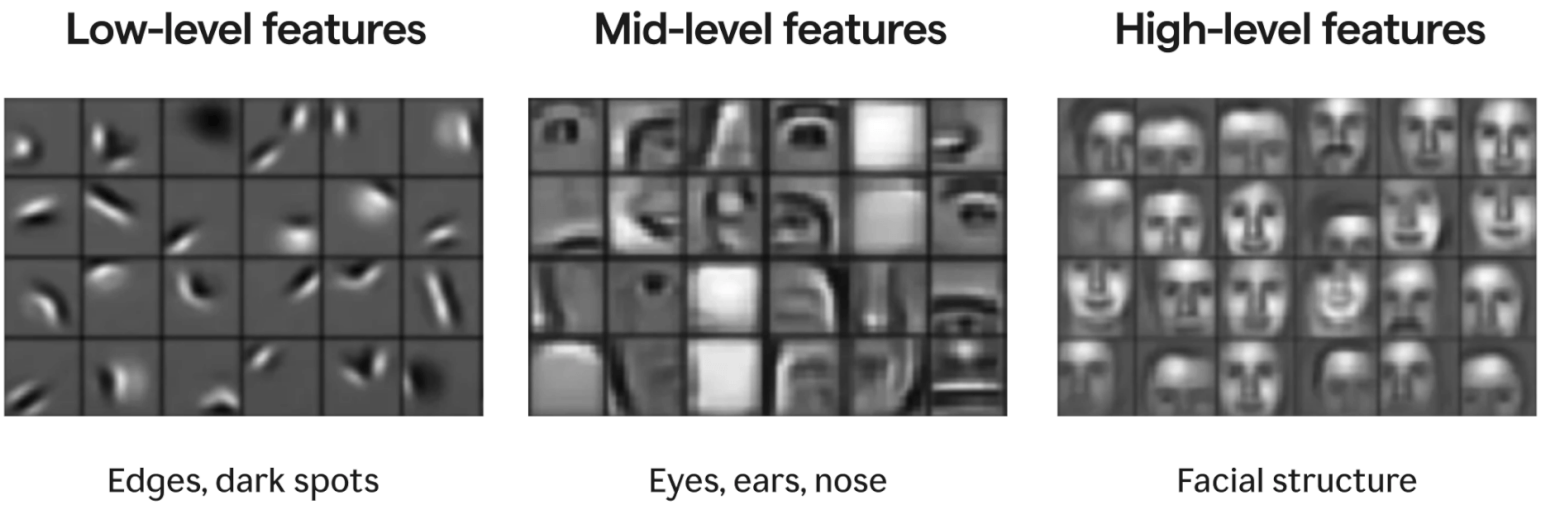
- Teacher:
  - Large model (U-Net++)
  - High accuracy
  - Slow
- Student:
  - Smaller model (Light U-Net)
  - Faster
  - Less accurate

Knowledge Distillation

- Train a small model using a large model
- Student learns from:
  - Ground truth labels
  - Teacher knowledge
- Goal: max performance with min cost

Feature-Based Distillation

- Match internal feature maps
- Not only final predictions
- Helps capture fine details
- Important for micro-crack detection



Training Idea

Combine two losses:

- Segmentation loss
- Distillation loss

Student learns from:

- Labels
- Teacher features

Evaluation Metrics

- IoU (Intersection over Union)
- F1 Score (Dice)
- Suitable for imbalanced data

Implementation Details
